RB-104 Payout writer runbook

Service

payout-writer sends approved payouts to the banking partner and records each transfer. It runs in eu-west-1 and us-east-1, four pods per region, in the payouts namespace.

Alert: PayoutWriterErrorRate

Fires when more than 1% of transfers fail for 5 minutes. Open the Payout Writer dashboard and check the partner error panel. Run payoutctl status --service payout-writer to see which pods are failing.

Mitigation

If one region fails and the other is healthy, take the failing region out of traffic with payoutctl pause --region eu-west-1 (or us-east-1). Pausing holds approved payouts in the queue; none is sent twice.

Rollback

If the errors started after a deploy, roll back first: kubectl rollout undo deployment/payout-writer -n payouts. Partner errors that started without a deploy are not fixed by a rollback.

Partner outage

When the banking partner's status page shows an incident, do not retry by hand. Payouts wait in the queue and payout-writer retries every 10 minutes for 24 hours. Tell support the expected delay.
