RB-101 Ledger writer runbook

Service

ledger-writer takes settled payment events from Kafka and writes them to the ledger-pg cluster. It runs in eu-west-1 and us-east-1, six pods per region, in the payments namespace.

Alert: LedgerWriterErrorRate

Fires when more than 2% of writes fail for 5 minutes. Open the Ledger Writer dashboard and check the error panel by region. Run ledgerctl status --service ledger-writer to see which pods are failing and why.

Mitigation

If one region fails and the other is healthy, take the failing region out of traffic with ledgerctl drain --region eu-west-1 (or us-east-1). Draining holds new events in Kafka; nothing is lost. Undrain with ledgerctl undrain once the region is healthy.

Rollback

If the errors started within an hour of a deploy, roll back first and investigate after: kubectl rollout undo deployment/ledger-writer -n payments. Watch the error panel for ten minutes before you call it fixed.

Escalation

If the error rate is still above 2% after 20 minutes, page the database team in #payments-db with the dashboard link and the output of ledgerctl status.
